Create a Python Virtual Environment for Jupyter Notebooks

Owned by Ryan Seaman

If a pre-existing Python module does not have all the packages you need, you can create a virtual environment to create a user-managed, semi-isolated location for additional packages. This can be used with Jupyter Notebooks with a couple extra steps.

1. SSH into submit0 and load the Python module for the version of Python you want to use:

```
module load Python/3.11.5-GCCcore-13.2.0
```

2. Create a virtual environment:

```
virtualenv my-virt-env
```

3. Activate the virtual environment:

```
source my-virt-env/bin/activate
```

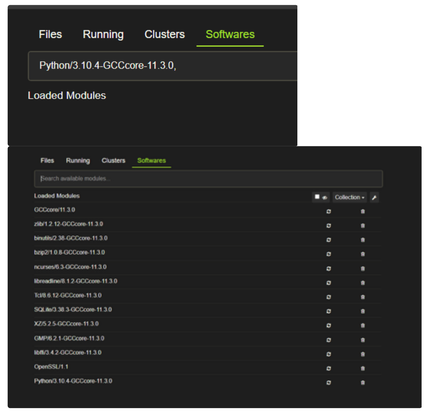

4. Install the ipykernel package and register the virtual environment as a new kernel:

```
pip install ipykernel
python -m ipykernel install --name my-python-env --display-name "Custom Python envi
```

With the pip command above, you can install additional packages at the same time as ipykernel. You could also use a requirements file if you know what you need and don't want to type it all out using:

```
pip install -r <path to requirements file>
```

5. Navigate to workbench.laureateinstitute.org and launch a new Jupyter Notebook session
6. Click on the “Softwares“ tab and load the module you used earlier when creating the virtual environment

7. You can now create a new notebook using your virtual environment
